Wear Resistance for Tablet Punches

Wear happens. Beamalloy’s patented Ion Beam Enhanced Deposition (IBED) surface treatments will help you improve your productivity by slowing it down. The result can be measured in real cost savings, increased production, and improved product quality.

Material Matters. Taber Abraser wear testing clearly shows relative improvements in wear resistance of specific metal and ceramic surface treatments over standard and specialty metal tooling steels. Dramatic and destructive, this testing demonstrates the relative performance of various coatings.

Process Matters. Just like a bad paint job with the world’s best paint, performance results are highly dependent on application of any surface treatment. Whether it’s chrome or titanium nitride, Beamalloy’s IBED process delivers the best performance possible with the right material for your application.

A variety of coatings, designed to improve wear- and corrosion-resistance are available for use on pharmaceutical tableting punches. To the extent that these coatings preserve the original finish of the working surfaces of the punches they can also act to help reduce sticking and picking. Hard refractory nitride coatings such as Titanium Nitride and Chromium Nitride are deposited by using Beamalloy’s IBED process at temperatures low enough to eliminate the dimensional distortion or bulk softening of the punch. When tableting formulations containing abrasive components, the use of Beamalloy IBED coatings can dramatically reduce tool wear and the need for continuous punch cleaning and re-polishing.
